Abstract

1. Introduction

Algebras can often be used to evaluate expressions. However, sometimes we might want to compose algebras together to provide multiple interpretations, especially when the construction of one algebra depends on another. In the context of Embedded Domain Specific Languages (DSL), Jeremy Gibbons [?] proposed two approaches on F-Algebra to tackle the problems of compositionality and dependencies. We will examine the two approaches in detail in section 4. In this paper, we will also use F-Algebra as the primary representation of algebras. In section 6, we will show that the problem can be handled using other representations of algebras as well.

2. DSL for parallel prefix circuits

3. F-Algebras

The circuit mentioned above can be represented using F-Algebras. The shape of the circuit is given by functor *CircuitF* as follows, where *r* marks the recursive spots:

```
data CircuitF r =  
  IdentityF Int  
  | FanF Int  
  | AboveF r r  
  | BesideF r r  
  | StretchF [Int] r  
  deriving Functor
```

We can recover the *Circuit* datatype from its shape functor *CircuitF*:

```
data Circuit = In (CircuitF Circuit)
```

An algebra for *CircuitF* consists of a type *a* and a function taking a *CircuitF* of *a*-values to an *a*-value:

```
type CircuitAlg a = CircuitF a → a
```

Suppose we want to obtain the width of a circuit, we can pick *Width* as our evaluation target (i.e. the carrier type of the algebra *widthAlg*):

```
type Width = Int
```

```
widthAlg :: CircuitAlg Width  
widthAlg (IdentityF w) = w  
widthAlg (FanF w)      = w  
widthAlg (AboveF x y) = x  
widthAlg (BesideF x y) = x + y  
widthAlg (StretchF xs x) = sum xs
```

widthAlg here will give us the final evaluation result (i.e. the width) of a circuit, assuming all children of *AboveF*, *BesideF* and *StretchF* are already evaluated and are of type *Width*.

Similarly, we can define *depthAlg* to get the depth of a circuit:

```
type Depth = Int
```

```
depthAlg :: CircuitAlg Depth  
depthAlg (IdentityF w) = 0  
depthAlg (FanF w)      = 1  
depthAlg (AboveF x y) = x + y  
depthAlg (BesideF x y) = x 'max' y  
depthAlg (StretchF xs x) = x
```

Given a nested circuit, we also need to define a fold to traverse the recursive data structure, using the algebra defined earlier for evaluation at each recursive step:

```
fold :: CircuitAlg a → Circuit → a  
fold alg (In x) = alg (fmap (fold alg) x)
```

Now a compositional observation function for our circuit can be defined as:

```
width :: Circuit → Width  
width = fold widthAlg
```

In order to conveniently construct circuits with *CircuitF*, we define the following smart constructors:

```
identity :: Int → Circuit  
identity = In ∘ IdentityF
```

```
fan :: Int → Circuit  
fan = In ∘ FanF
```

```
above :: Circuit → Circuit → Circuit  
above x y = In (AboveF x y)
```

```
beside :: Circuit → Circuit → Circuit  
beside x y = In (BesideF x y)
```

```
stretch :: [Int] → Circuit → Circuit  
stretch xs x = In (StretchF xs x)
```

Therefore, the Brent-Kung parallel prefix circuit in Figure 1 can be constructed as:

```
circuit1 = above (beside (fan 2) (fan 2))  
            (above (stretch [2, 2] (fan 2))  
                  (beside (identity 1) (beside (fan 2) (identity 1))))
```

4. Existing Approaches

To allow multiple interpretations and dependent interpretations, Jeremy Gibbons proposed two approaches based on F-Algebra. The first one is to construct a tuple as the semantics of an expression and project the desired interpretation from the tuple. The second one uses church encoding to provide a universal generic interpretation.

4.1 Pairs for multiple interpretations with dependencies

While it is straightforward to add additional interpretations that are independent of previously defined ones [?], adding an interpretation that depends on 'secondary' interpretations of its parts can be tricky.

For example, whether a circuit is well formed or not depends on the widths of its constituent parts. Since the interpretation is non-compositional [?], there is no corresponding *CircuitAlg*. To allow multiple interpretations with dependencies using algebras, Gibbons [?] proposed the following *zygomorphism* [?], making the semantic domain of the interpretation (i.e. the carrier type of the algebra) a pair:

```
type WellSized = Bool
```

```
wswAlg :: CircuitAlg (WellSized, Width)
wswAlg (IdentityF w) = (True, w)
wswAlg (FanF w)      = (True, w)
wswAlg (AboveF x y) = (fst x && fst y && snd x == snd y, snd x)
wswAlg (BesideF x y) = (fst x && fst y, snd x + snd y)
wswAlg (StretchF ws x) = (fst x && length ws == snd x, sum ws)
```

Individual interpretations can then be recovered as follows:

```
wellSized1 :: Circuit → WellSized
wellSized1 x = fst (fold wswAlg x)
```

```
width1 :: Circuit → Width
width1 x = snd (fold wswAlg x)
```

4.2 Church encoding for multiple interpretations

From the previous section we can see that it is possible to provide multiple interpretations by pairing semantics up and projecting the desired interpretation from the tuple. However, it is still clumsy and not modular: existing code needs to be revised every time a new interpretation is added. Moreover, for more than two interpretations, we have to either create combinations for each pair of interpretations, or use tuples which generally lack good language support.

Therefore, Gibbons [?] presented a single parametrized interpretation, which provides a universal generic interpretation as the *Church encoding*:

```
newtype Circuit1 = C1 { unC1 :: ∀a. CircuitAlg a → a }
```

```
identity1 w = C1 (λalg → alg (IdentityF w))
fan1 w      = C1 (λalg → alg (FanF w))
above1 x y  = C1 (λalg → alg (AboveF (unC1 x alg) (unC1 y alg)))
beside1 x y = C1 (λalg → alg (BesideF (unC1 x alg) (unC1 y alg)))
stretch1 ws x = C1 (λalg → alg (StretchF ws (unC1 x alg)))
```

Then it can specialize to *width* and *depth*:

```
width2 :: Circuit1 → Width
width2 x = unC1 x widthAlg
```

```
depth2 :: Circuit1 → Depth
depth2 x = unC1 x depthAlg
```

However, one big problem with the above church encoding approach is that it does not support dependent interpretations.

5. Composable Algebras

To allow composing algebras modularly, we first use the following type class to state that a semantic domain of type *i* is part of a larger collection of types:

```
class i <: e where
  inter :: e → i
```

Here *i <: e* means that *i* is a component of *e*, and gives the corresponding projection functions as follows:

```
instance i <: i where
  inter = id
```

```
instance i <: (Compose i i2) where
  inter = fst
```

```
instance (i <: i2) ⇒ i <: (Compose i1 i2) where
  inter = inter ∘ snd
```

Then we introduce the operator (*< + >*) that takes two algebras as inputs and gives back an algebra with a composed carrier type.

```
type Compose i1 i2 = (i1, i2)
```

```
(< + >) :: CircuitAlg a → CircuitAlg b → CircuitAlg (Compose a b)
(< + >) a1 a2 (IdentityF w) = (a1 (IdentityF w), a2 (IdentityF w))
(< + >) a1 a2 (FanF w)      = (a1 (FanF w), a2 (FanF w))
(< + >) a1 a2 (AboveF x y) =
  (a1 (AboveF (inter x) (inter y)), a2 (AboveF (inter x) (inter y)))
(< + >) a1 a2 (BesideF x y) =
  (a1 (BesideF (inter x) (inter y)), a2 (BesideF (inter x) (inter y)))
(< + >) a1 a2 (StretchF xs x) =
  (a1 (StretchF xs (inter x)), a2 (StretchF xs (inter x)))
```

Since now a circuit can be made up of subcircuits with composed semantic domain, we need to slightly modify our constructs of algebras. With the help of the *newtype* wrapper which is needed to allow multiple interpretations over the same underlying type, we define *gwidth* and *gdepth* to help us retrieve the target evaluation type from a composed type:

```
newtype Width2 = Width2 { width :: Int }
newtype Depth2 = Depth2 { depth :: Int }
```

```
gwidth :: (Width2 <: e) ⇒ e → Int
gwidth = width ∘ inter
```

```
gdepth :: (Depth2 <: e) ⇒ e → Int
gdepth = depth ∘ inter
```

Then we can define *widAlg2* and *depthAlg2* as:

```
widthAlg2 :: CircuitAlg Width2
widthAlg2 (IdentityF w) = Width2 w
widthAlg2 (FanF w)      = Width2 w
widthAlg2 (AboveF x y) = Width2 (gwidth x)
widthAlg2 (BesideF x y) = Width2 (gwidth x + gwidth y)
widthAlg2 (StretchF xs x) = Width2 (sum xs)
```

```
depthAlg2 :: CircuitAlg Depth2
depthAlg2 (IdentityF w) = Depth2 0
depthAlg2 (FanF w)      = Depth2 1
depthAlg2 (AboveF x y) = Depth2 (gdepth x + gdepth y)
depthAlg2 (BesideF x y) = Depth2 (gdepth x + 'max' gdepth y)
depthAlg2 (StretchF xs x) = Depth2 (gdepth x)
```

Now it is straightforward to compose algebras together:

`cAlg = widthAlg2 < + > depthAlg2`

`cAlg` is composed of `widthAlg2` and `depthAlg2`, with a carrier type of `(Compose Width2 Depth2)`.

The observation functions for our circuit can be defined as:

`width3 :: Circuit → Int`
`width3 x = gwidth (fold cAlg x)`

`depth3 :: Circuit → Int`
`depth3 x = gdepth (fold cAlg x)`

6. Dependent Algebras

In the previous section we talked about how algebras can be composed together to allow multiple interpretations. In this section, we will introduce an approach that allows multiple interpretations with dependencies. With our approach, each property we want to evaluate has a corresponding algebra. There is no need to construct a pair of interpretations when one depends on the other. For example, unlike `wsAlg` in section 4.1, we have `wsAlg` that corresponds to `wellSized`, where the definition of `widthAlg` is no longer needed.

The first step is to change our definition of algebra from `CircuitAlg` to `GAlg`:

`type GAlg r a = CircuitF r → a`

`GAlg` stands for *generic algebra*. It consists of two types `r` and `a`, and a function taking `CircuitF` of `r`-values to an `a`-value, where `a <: r`. For `wsAlg`, the first type `r` represents a collection of types that contains both `WellSized2` and `Width2` (specified by `(WellSized2 <: r, Width2 <: r)`). Since each child of `AboveF`, `BesideF` and `StretchF` is of type `r`, `gwidth` can be used to retrieve the width of a circuit. Therefore, `wsAlg` can be defined as follows:

`newtype WellSized2 = WellSized2 { wellSized :: Bool }`

`wsAlg :: (WellSized2 <: r, Width2 <: r) ⇒ GAlg r WellSized2`
`wsAlg (IdentityF w) = WellSized2 True`
`wsAlg (FanF w) = WellSized2 True`
`wsAlg (AboveF x y) =`
`WellSized2 (gwellSized x && gwellSized y && gwidth x == gwidth y)`
`wsAlg (BesideF x y) =`
`WellSized2 (gwellSized x && gwellSized y)`
`wsAlg (StretchF xs x) =`
`WellSized2 (gwellSized x && length xs == gwidth x)`

Here we also need the `(< + >)` operator for composing two algebras together for dependent interpretations with `fold`. While it is very similar to the one defined in the previous section, we need to specify the relationships between types of algebras we are composing. Given an algebra from type `r` to type `a`, and another from type `r` to type `b`, where `r` contains both `a` and `b`, it gives back a new algebra from type `r` to type `(Compose a b)`.

`(< + >) :: (a <: r, b <: r) ⇒ GAlg r a → GAlg r b →`
`GAlg r (Compose a b)`
`(< + >) a1 a2 (IdentityF w) =`
`(a1 (IdentityF w), a2 (IdentityF w))`
`(< + >) a1 a2 (FanF w) =`
`(a1 (FanF w), a2 (FanF w))`
`(< + >) a1 a2 (AboveF x y) =`
`(a1 (AboveF (inter x) (inter y)), a2 (AboveF (inter x) (inter y)))`
`(< + >) a1 a2 (BesideF x y) =`
`(a1 (BesideF (inter x) (inter y)), a2 (BesideF (inter x) (inter y)))`
`(< + >) a1 a2 (StretchF xs x) =`
`(a1 (StretchF xs (inter x)), a2 (StretchF xs (inter x)))`

Now we can define `cAlg2` that is composed of `widthAlg2` and `wsAlg`:

`cAlg2 = widthAlg2 < + > wsAlg`

With observation functions `width2` and `wellSized2` defined as:

`width2 :: Circuit → Int`
`width2 x = gwidth (fold cAlg2 x)`

`wellSized2 :: Circuit → Bool`
`wellSized2 x = gwellSized (fold cAlg2 x)`

7. Extensibility in Both Dimensions

So far we have only talked about extensibility in one dimension, namely, how to add new observation functions in a modular way with algebras for our DSL. What if we want to have extensibility in a second dimension, which is to extend our grammar by adding new constructors modularly? To make the problem more interesting, these additional constructors may also bring dependencies in their corresponding observation functions at the same time. In this section, we will show that our approach of composing algebras while incorporating dependencies works well with the Modular Reliable Matching (MRM) approach, which allows us to add additional constructors modularly. We will present a two-level composition of algebras: for each modular component, we compose its algebras together if an interpretation is dependent; for different components, we combine their corresponding algebras together to allow evaluation of a composed data structure.

For example, say at first we only have three constructs in our DSL of circuits: *Identity*, *Fan*, and *Beside*. We can define a functor *CircuitFB* to represent this datatype, where *B* stands for *Base*:

`data CircuitFB r =`
`Identity Int`
`| Fan Int`
`| Beside r r`
`deriving Functor`

There are no dependencies involved for the algebras of this circuit, with only *Identity*, *Fan* and *Beside*, whether a circuit is well formed or not is not dependent on the width of its parts. However, we will keep our representation for dependent algebras to be consistent with algebras we will later define for extended datatypes:

`type GAlGB r a = CircuitFB r → a`

Algebras for *width* and *wellSized* are exactly the same as before:

`widthAlGB :: (Width2 <: r) ⇒ CircuitFB r → Width2`
`widthAlGB (Identity w) = Width2 w`
`widthAlGB (Fan w) = Width2 w`
`widthAlGB (Beside x y) = Width2 (gwidth x + gwidth y)`

`wsAlGB :: (Width2 <: r, WellSized2 <: r) ⇒`
`CircuitFB r → WellSized2`
`wsAlGB (Identity w) = WellSized2 True`
`wsAlGB (Fan w) = WellSized2 True`
`wsAlGB (Beside x y) = WellSized2 (gwellSized x && gwellSized y)`

Now suppose we want to extend our circuits by adding new constructs *Above* and *Stretch*. We add the datatype constructors as a functor *CircuitFE*, where *E* stands for *Extended*:

`data CircuitFE r =`
`Above r r`
`| Stretch [Int] r`
`deriving Functor`

Algebras correspond to this functor are similar to the ones above. The only difference is that the interpretation for checking if a circuit is well formed now depends on the widths of its part. Same as in section 6, we use *gwidth* to retrieve the width of a circuit:

```
type GAlGE r a = CircuitFE r → a

widthAlGE :: (Width2 <: r) ⇒ CircuitFE r → Width2
widthAlGE (Above x y) = Width2 (gwidth x)
widthAlGE (Stretch xs x) = Width2 (sum xs)

wsAlGE :: (Width2 <: r, WellSized2 <: r) ⇒
CircuitFE r → WellSized2
wsAlGE (Above x y) =
  WellSized2 (gwellSized x && gwellSized y && gwidth x == gwidth y)
wsAlGE (Stretch xs x) =
  WellSized2 (gwellSized x && length xs == gwidth x)
```

Unlike the $< + >$ operator defined in previous sections, here we associate it with a type class to compose algebras corresponding to different functors. With this approach, we don't have to define a different operator for algebra composition each time a new functor is added. Instead, all we have to do is to make a new instance of type class *Comb* and define the corresponding behavior of $< + >$. Since we have two functors *CircuitFB* and *CircuitFE*, we create two instances of *Comb* and define $< + >$ for each of them:

```
class Comb f r a b where
  (< + >) :: (f r → a) → (f r → b) → (f r → (Compose a b))

instance (a <: r, b <: r) ⇒ Comb CircuitFB r a b where
  (< + >) a1 a2 (Identity w) = (a1 (Identity w), a2 (Identity w))
  (< + >) a1 a2 (Fan w)      = (a1 (Fan w), a2 (Fan w))
  (< + >) a1 a2 (Beside x y) =
    (a1 (Beside (inter x) (inter y)), a2 (Beside (inter x) (inter y)))

instance (a <: r, b <: r) ⇒ Comb CircuitFE r a b where
  (< + >) a1 a2 (Above x y) =
    (a1 (Above (inter x) (inter y)), a2 (Above (inter x) (inter y)))
  (< + >) a1 a2 (Stretch xs x) =
    (a1 (Stretch xs (inter x)), a2 (Stretch xs (inter x)))
```

A circuit with all five constructs can be built from the modular components. First we define the type of the circuit:

```
type Circuit2 = Fixc[CircuitFB, CircuitFE]
```

The type *Circuit2* denotes circuits that have *Identity*, *Fan*, *Beside*, *Above* and *Stretch* as their components.

Since *Width2* needs to be part of the carrier type of *wsAlGE* such that we can retrieve the width of a circuit and test if it is well-formed, for *CircuitFE*, we need to compose *widthAlGE* and *wsAlGE* together and use *compAlGE* for evaluation.

```
compAlGE = widthAlGE < + > wsAlGE
```

Then we use $(::)$ to combine algebras correspond to different functors together $[?]$. Since the algebras in the list constructed by $(::)$ need to have the same carrier return type, we compose *widthAlGB* and *wsAlGB* for *CircuitFB* and get *compAlGB*:

```
compAlGB = widthAlGB < + > wsAlGB
```

The *fold* operator defined in MRM library $[?]$ takes an fs-algebra and *Fix fs* arguments. Then we define the evaluation function for our circuit as a fold using the combined algebras:

```
eval :: Circuit2 → Compose Width2 WellSized2
eval = fold (compAlGB :: (compAlGE :: Void))
```

Individual interpretations can then be retrieved by *gwidth* and *gwellSized*:

```
width3 :: Circuit2 → Int
width3 = gwidth ∘ eval

wellSized3 :: Circuit2 → Bool
wellSized3 = gwellSized ∘ eval
```

They can be used with smart constructors to evaluate a concrete circuit:

```
c1 = above (beside (fan 2) (fan 2))
      (above (stretch [2, 2] (fan 2))
        (beside (identity 1) (beside (fan 2) (identity 1))))
test1 = width3 c1
test2 = wellSized3 c1
```

8. Other representations of algebra

8.1 Type Class with Proxies

```
data Proxy a = Proxy
```

```
class Circuit inn out where
  identity :: Proxy inn → Int → out
  fan      :: Proxy inn → Int → out
  above    :: inn → inn → out
  beside   :: inn → inn → out
  stretch :: [Int] → inn → out
```

```
instance (Circuit inn Width2, Width2 <: inn) ⇒
Circuit inn Width2 where
  identity (Proxy :: Proxy inn) w = Width2 w
  fan (Proxy :: Proxy inn) w = Width2 w
  above x y = Width2 (gwidth x)
  beside x y = Width2 (gwidth x + gwidth y)
  stretch xs x = Width2 (sum xs)
```

```
instance (Circuit inn WellSized2,
  Width2 <: inn,
  WellSized2 <: inn) ⇒ Circuit inn WellSized2 where
  identity (Proxy :: Proxy inn) w = WellSized2 True
  fan (Proxy :: Proxy inn) w = WellSized2 True
  above x y = WellSized2 (gwellSized x && gwellSized y &&
    gwidth x == gwidth y)
  beside x y = WellSized2 (gwellSized x && gwellSized y)
  stretch xs x = WellSized2 (gwellSized x &&
    length xs == gwidth x)
```

```
instance (Circuit inn inn1, Circuit inn inn2) ⇒
Circuit inn (Compose inn1 inn2) where
  identity (Proxy :: Proxy inn) w =
    ((identity (Proxy :: Proxy inn) w) :: inn1,
     (identity (Proxy :: Proxy inn) w) :: inn2)
  fan (Proxy :: Proxy inn) w =
    ((fan (Proxy :: Proxy inn) w) :: inn1,
     (fan (Proxy :: Proxy inn) w) :: inn2)
  above x y = ((above x y) :: inn1, (above x y) :: inn2)
  beside x y = ((beside x y) :: inn1, (beside x y) :: inn2)
  stretch xs x = ((stretch xs x) :: inn1, (stretch xs x) :: inn2)
```

```
type ComposedType = Compose Width2 WellSized2
```

```

gfan w      =
  fan (Proxy :: Proxy ComposedType) w :: ComposedType
gidentity w =
  identity (Proxy :: Proxy ComposedType) w :: ComposedType
gbeside x y = (beside x y) :: ComposedType
gabove x y = (above x y) :: ComposedType
gstretch xs x = (stretch xs x) :: ComposedType

```

```

c = (gfan 2 'gbeside' gfan 2) 'gabove'
  gstretch [2, 2] (gfan 2) 'gabove'
  (gidentity 1 'gbeside' gfan 2 'gbeside' gidentity 1)

```

```

width4 :: (Width2 <: e) => e -> Int
width4 = gwidth

```

```

wellSized4 :: (WellSized2 <: e) => e -> Bool
wellSized4 = gwellSized

```

```

cAlg :: Circuit (Compose Width2 WellSized2)
  (Compose Width2 WellSized2)
cAlg = widthAlg < + > wsAlg

```

```

cidentity = identity cAlg
cfan = fan cAlg
cabove = above cAlg
cbeside = beside cAlg
cstretch = stretch cAlg

```

```

c = (cfan 2 'cbeside' cfan 2) 'cabove'
  cstretch [2, 2] (cfan 2) 'cabove'
  (cidentity 1 'cbeside' cfan 2 'cbeside' cidentity 1)

```
